Re: CUSTOMER NOTIFICATION

Dear Customer,

Trenton Municipal Utilities Water Department takes great pride in providing safe drinking water to the community. We routinely perform various tests to verify the water is meeting Missouri Department of Natural Resources (DNR) requirements.

During recent testing in September for lead and copper, we tested 20 locations throughout the city. Three of the test locations showed lead levels above the allowable level, the 17 other locations did not. It is also important to note that the three locations all had lead service pipes connecting the house to the water main system. All 20 locations that were tested are being notified of their test results.

We have reviewed our treatment operations with DNR and the water leaving the plant meets federal and state water quality standards.

Testing shows that not all areas of the city have elevated levels. We are working with DNR to identify the cause of the elevated lead levels, identify customers affected, and develop a course of action to reduce levels for those customers. We are also going to double the number of test locations and increase testing frequency until this issue is resolved.

We encourage you to review the attached information from the DNR. It contains simple and effective steps you can take to address lead in your home or business. The city has established a hotline (660) 234-9172 for residents to call if they have questions.

We want you to know we are working diligently to provide high quality water to our community and will be updating the public throughout this process.

Sincerely,

A handwritten signature in black ink that reads "Ronald R. Urton".

Ron Urton, PE
City Administrator/Utility Director

City of Trenton PWSD ID # MO2010796

The U.S. Environmental Protection Agency, Missouri Department of Natural Resources and the City of Trenton (Water Supply ID # MO2010796) are concerned about lead in your drinking water. Three samples collected in the June to September 2017 monitoring period have tested higher than allowed for lead. EPA and the department have set an action level of 15 ppb, or 0.015 milligrams of lead per liter of water (mg/L). If you have any questions about how we are carrying out the requirements of the lead regulation, please give us a call at 660-234-9172. This flyer explains the simple steps you can take to protect yourself and your family from exposure to lead in drinking water.

Important Information about Lead in Your Drinking Water

The City of Trenton found elevated levels of lead in drinking water in three of twenty homes tested. Lead can cause serious health problems, especially for pregnant women and young children. Please read this information closely to see what you can do to reduce lead in your drinking water.

Health Effects of Lead

Lead can cause serious health problems if too much enters your body from drinking water or other sources. It can cause damage to the brain and kidneys and can interfere with the production of red blood cells that carry oxygen to all parts of the body. The greatest risk of lead exposure is to infants, young children and pregnant women. Scientists have linked the effects of lead on the brain with lowered IQ in children. Adults with kidney problems and high blood pressure can be affected by low levels of lead more than healthy adults. Lead is stored in the bones and can be released later in life. During pregnancy the child receives lead from the mother's bones, which may affect brain development.

Lead is a common metal found throughout the environment in lead-based paint, air, household dust, food, certain types of pottery, porcelain, pewter, crystal, and water. Lead can pose a significant risk to your health if too much enters your body. Lead builds up in the body over many years and can cause damage to the brain, red blood cells and kidneys. The greatest risk is to young children (especially under age 6), pregnant women and their fetuses. Amounts of lead that do not appear to hurt adults can slow down the normal mental and physical development of growing bodies. In addition, a child at play often comes into contact with sources of lead contamination, like dirt and dust that rarely affect an adult. If children put dirty fingers in their mouths (as most children do) some lead may be absorbed into the children's systems. It is important to wash children's hands and toys often and try to make sure they only put food in their mouths.

Lead in Drinking Water

Lead in drinking water, although rarely a sole cause of lead poisoning, can significantly increase a person's total lead exposure, particularly the exposure to infants who drink baby formulas and concentrates that are mixed with water. EPA estimates that drinking water can make up 20 percent or more of a person's total exposure to lead. Boiling water does not reduce lead levels.

How Lead Enters Our Water

Lead is unusual among drinking water contaminants in that it seldom occurs naturally in water supply wells. In most systems, lead enters drinking water as a result of corrosion of materials containing lead in the water distribution system and plumbing. These materials include lead-based solder used to join copper pipe, brass and in some cases, pipes made of lead that connect your house to the water main (service lines). In 1986, Congress banned the use of lead solder containing greater than 0.2 percent lead and restricted the lead content of faucets, pipes and other plumbing materials to 8.0 percent. Because of this, faucets are sometimes the main source of lead in the type of samples we take. In 2011, Congress further reduced the lead content of faucets, pipes and other plumbing materials to 0.25 percent. The effective date for the new requirement was January 4, 2014.

When water stands in lead pipes or plumbing systems containing lead for several hours or more, the lead in the pipes or solder may dissolve into your drinking water. This means the first water drawn from the tap in the morning, or after a period of absence, can contain fairly high levels of lead. Flushing the tap after a sitting time as explained above can significantly reduce the lead content in drinking water.

What You Can Do

- 1) Purchase bottled water for cooking and drinking.**
- 2) Flush the tap for one to two minutes before using the water for drinking or cooking.** Doing this reduces the level of lead and copper because it flushes away the water that has been sitting in pipes or against the fittings.
- 3) Purchase or lease a home treatment device.** Treatment devices are limited in that each unit treats only the water that flows from the faucet which it is connected. All these devices require maintenance and replacement. Devices such as reverse osmosis systems or distillers can effectively remove lead from your drinking water. Some activated carbon filters may reduce lead levels at the tap; however, all lead reduction claims should be investigated. Be sure to check the actual performance of a specific treatment device before and after installing a unit.

What We Have Done to Reduce Lead

Three out of Twenty homes tested had elevated lead levels. We are working with the Missouri Department of Natural Resources to resolve this problem.

For More Information

A variety of sources are available for additional information:

- Your Family Doctor can perform a blood test for lead and provide information about the health effects of lead.
- We encourage you to flush your taps very well before consuming the water if it has not been used for a day or more.
- The Missouri Department of Health and Senior Services in Jefferson City can provide information on the health effects of lead exposure and steps to avoid environmental lead exposure. Their number is 573-751-6102.
- Specific Information on lead in drinking water at a water system can be obtained by calling the Missouri Department of Natural Resources, Public Drinking Water Branch at 1-800-361-4827 or 573-751-1406.
